Answer to the required question:

The function of this node is to act as the bridge between ROS and the robot in Webots. It subscribes to the `cmd_vel` topic using `geometry_msgs/Twist`, which means it's listening for velocity commands (linear and angular). When it receives those commands, it converts them into left and right wheel speeds. Thus the robot can move linearly from `linear.x` and rotate from `angular.z`.

Screenshot showing the Webots simulation and the terminal with the published command (results of steps 14 and 15):

NOTE!!: Despite extensive troubleshooting with the VM network settings, I keep getting these errors which means Webots cannot access the internet, so it cannot download the three `EXTERNPROTO` files from GitHub. The robot controller is still connecting, but the world file is failing to load those background/floor objects. This despite my VM saying that it is connected via NAT.
